tape is applied. A face plate **44** is shown in FIG. 6 which also illustrates how a pressure roll may be locked in adjusted position by means of the wing nut **33** on the threaded end of member **42** which extends through the frame. As shown each pressure roll comprises a sleeve **48** adjustable axially of member **42** for moving the pressure roll toward and away from the supporting frame.

There has thus been provided a device in which the objects of the invention are acomplished in a simple and practical way.

I claim:

1. Apparatus for applying tape to a first surface adjoining, and angularly related to, a second surface, comprising, a carriage having a body and wheels on which the body is mounted, and means for mounting the wheels on horizontal axles to travel on said second surface, said body having means for mounting a roll of tape for rotation in a plane parallel with the plane of the second surface over which the carriage is moved, guide means, and pressure means for directing tape laterally as it is unwound from the tape roll and applying it on the first surface as the carriage is moved over the second surface.

2. The apparatus claimed in claim **1** including means for adjusting the position of the pressure means relative to the inner edge of tape being unwound from the tape roll and applied to a surface.

3. Apparatus for applying tape to a first surface adjoining, and angularly related to, a second surface, comprising, a carriage having a body and wheels on which the body is mounted, said body having means for mounting a roll of tape for rotation in a plane parallel with the plane of a surface over which the carriage is moved, guide means, and pressure means for directing tape as it is unwound from the tape roll and applying it on the first surface as the carriage is moved over the second surface and, wheel mounting means adjustable toward and away from a surface over which the carriage is moved to compensate for differences in width of rolls of tape and to control the position of a roll of tape on the carriage so that it is disposed close to the said second surface over which the carriage is moved and in position to deliver tape laterally from the carriage to be applied on the adjoining first surface with an edge of the tape in substantially abutting relation to the said second surface over which the carriage is moved.

4. Apparatus for applying tape to a first surface adjoining, and angularly related to, a second surface, comprising, a carriage having a body and wheels on which the body is mounted, said body having means for mounting a roll of tape for rotation in plane parallel with the plane of a surface over which the carriage is moved, guide means, and pressure means for directing tape as it is unwound from the tape roll and applying it on the first surface as the carriage is moved over the second surface, the means for mounting a roll of tape being such that a roll of tape may be mounted thereon for delivering tape either to the left or right of the carriage, and may be reversed on the mounting means for changing the direction of tape delivery, two pairs of guide and pressure means, mounted along the respective lateral edges of the said body, each pair comprising a guide roll and an applicator roll and each guide roll and each applicator roll being mounted on an axis which is at right angles to the axis of the wheels of the carriage.

5. The apparatus claimed in claim **4** having also cutters on the frame slightly to the rear of said guide rolls respectively and between said rolls and the periphery of a roll of tape mounted on the carriage.
